

CivicFlow AI.

From green ambition
to interoperable action

Born from a real problem

A REAL MUNICIPALITY

Bosa, Sardinia. A small coastal municipality with green ambitions

REAL REGIONAL FUNDS

Regional transition funds were available. EU green mobility programmes were open. Budget existed. The opportunity was real and time-bound.

NO PROJECT, NO FUNDING

Without a credible, structured project architecture, funds could not be accessed. The bottleneck was not ambition. It was the missing technical map.

The Municipal Bottleneck

Many Actors

Municipality, mobility operators, energy utilities, EV networks, citizens.

Fragmented Systems

Transport APIs, charging protocols, payments, data platforms.

Missing project architecture

No shared map. No aligned standards. No pilot-ready plan.

Use Case: Municipal Green Mobility

01 The Need

A municipality has green-transition funds, but no shared technical map to turn them into a real pilot.

02 Our Specialized Agent

CivicFlow is focused on urban mobility and green transition: public transport, EV charging, energy actors, citizens, and data platforms.

03 The goal

Real not generic: grounded in verified standards and real local data.

What Happens Behind the UI

Agent

4 Tools

RAG

Guardrail

Jakarta EE 11, MicroProfile, Open Liberty, LangChain4j. Receives city + domain input. Orchestrates all downstream tool calls and validates final output structure.

- Web context retrieval
- EV charging
- Data connector
- Transitland API

Curated knowledge base: standards summaries, EU regulatory context, interoperability frameworks. Grounds every response in verified domain knowledge.

Verifies the JSON, rejects invented standards, keeps the waist narrow, and forces regeneration when the output is invalid. Bad architecture never reaches the user.

What CivicFlow Generates

Stakeholders

Municipality. Transport operators. Energy providers. EV networks. Citizens. Payment systems. Data platforms. Every actor that matters - mapped automatically.

Shared Capabilities

Multimodal routing. Ticketing. EV charging. Identity. Real-time data. Demand response. The minimum shared core that makes interoperability possible.

Standards + JSON

TOMP-API. GTFS. OCPP. OCPI. OpenADR. SIRI. GBFS. Verified, not invented. Output is structured JSON — ready to consume, extend, and reuse.

Live Demo

Your City

Let's test it live.

Why This Is Not Generic AI

Grounded in Reality

Verified standards, city-specific context, and real transit + EV charging data constrain every output. No invented architecture.

Anti-Hallucination by Design

A runtime guardrail validates every standard cited. If it falls outside the verified set, the system forces a correction automatically.

Why It Matters for Pilots

Faster First Architecture

From weeks of manual analysis to seconds. CivicFlow compresses the first architecture phase so pilots can begin with a credible technical map.

Better Stakeholder Alignment

A shared hourglass model gives municipalities, technical teams, and funding bodies a common language - ready to discuss, challenge, and improve.

Reusable Starting Point

Structured JSON output and verified standards mean every generated architecture becomes a reusable base for future pilots and regions.

Open-Source & Scalable Vision

01

One City

A single municipality generates its hourglass model. Local stakeholders, local standards, local pilot. Fast, grounded, reusable.

02

A Region

Multiple cities share a common interoperability layer. Regional mobility, energy grids, and data platforms aligned under one architecture.

03

A Continent

Cross-border infrastructure planning. Water networks, green corridors, EV roaming - mapped with the same structured method at continental scale.

04

Open Source

Core output is structured, documented, and public. Any city, any team, any domain can fork, extend, and reuse the architecture model.

Thank You
